

THE 70/20/10 RULE.

What actually determines the success of an AI project — and it is not the model you chose.

EFFORT VS. IMPACT DISTRIBUTION

1 WHAT IT MEASURES

This framework distributes the determinant factors of any AI initiative across three layers. **70% of outcomes depend on the people involved and process redesign** — not on tool selection. The 20% tech stack layer covers observability, orchestration and integrations. The remaining 10% corresponds to model selection and calibration — the part that gets the most attention while moving the needle the least.

2 HOW IT BREAKS DOWN IN PRACTICE

3 WHAT EACH PERCENTAGE MEANS

4 HOW TO APPLY IT IN PRACTICE

5 WHEN THE RULE DOES NOT APPLY

NEW REVENUE STREAM

When the project creates a new business line rather than automating an existing process, the process layer is smaller because the process does not yet exist. Weight shifts temporarily to stack and market validation.

PURE GENERATION TASKS (CODING, CONTENT CREATION)

For code agents or content generation without organisational process involved, model choice matters more — the 10% rises to 25–35%. The 70 rule applies to enterprise process automation.

Just as in cooking, the result depends 70% on ingredient quality and technique, not the stove. In AI, the model is the stove — invest where the impact is real.
